**Abstract** — *This article describes the design, and implementation of a prototype of a self-propelled material lifter with high payload capacity, used to lift materials to the roofs of two-story buildings. It uses a gravity clamping mechanism inspired by pole-climbing robots used to maintain highway light poles, wind turbines, and palm trees. This will solve the problem that homeowners and small business owners face when having to lift materials onto the rooftops. Current alternatives such as cranes, bucket trucks or scaffolding, lead to storage problems and excessive costs. This prototype is light enough for one person lift and compact enough to carry it on an average size car cargo area. These two characteristics are possible by utilizing economical lumber as the body structure. The machine will clamp the 2 x 6 lumber with an A shape point of contact and roll up its edges to the required height.*

**Key Terms** — *Climbing, friction, lifter, portable.*

## **PROBLEM STATEMENT**

In a residential energy study made by Worcester Polytechnic Institute showed that 84% of the surveyed Puerto Rican population's houses poses at least one AC unit in their homes and a 59% of the surveyed population poses two or more units [1]. The Compressor unit usually installed in roofs or high places weights between 28 to 97 lbs. depending on its capacity [2]. Because an Air Conditioning installer business requires minimum investment, most assistants part ways with their employers to start their own installing business. A high percentage of these installers start with minimum resources and see themselves in the situation of having to carry the AC components up a ladder or pull it up with a rope to the roof. This

practice represents a safety issue for the installer and the homeowner's property. In Puerto Rico approximately 42,000 photovoltaic systems have been installed on residential roofs, 10,000 of them just in 2022 [3]. Just like AC units, photovoltaics systems, roof sealing products, water heaters and roof repairs require lifting material and equipment to the roof with the same safety risk. Carrying a 5-gallon bucket of sealer or paint is not an easy task, especially if the house does not have access to the roof. The current alternatives are to place a ladder and carry the materials up the stairs, pull materials up using rope, or use scaffolds or heavy equipment to lift the material to the repair location. The problems with these solutions are that they represent a high safety risk or are expensive and difficult to store within the house. Hence, the idea is to investigate a portable lift machine that can be stored easily inside a closet or a storage box in the yard. The general idea is to design a portable machine capable of lifting 200 lbs. of material to 20-foot-tall roofs.

## **Research Description**

Regarding portable lifting machines, two main types of equipment jump out: a material lifter or stacker and a winch/hoist-style crane. The material lifter or stacker, on Figure 1 can be used in warehouses, factories, shipping facilities, supermarkets, and other industrial environments [4]. The lift consists of a hand-operated winch (also available motorized), which extends its steel body up to eighteen feet vertically. The benefits of this system are that it is a one-person operation, works from the floor up, and is portable [4]. Its downfall is the height is limited to the reach of the body. The portable crane, Figure 2, is available with a powerful motor also available as a hand crank [5]. This equipment consists of a steel frame that holds a steel

cable of various lengths and pulls material up. The benefits are its portability, and high payload hoisting capabilities [5]. The two concerns with the system are that it requires to be placed at the destination of the material and is limited by the amount of cable the reel can hold. Another equipment often utilized is the winch, Figure 3, by itself built into some sort of site-built structure [6]. The benefits are its portability, easy handling, versatility, and structure material regularly available within the construction site. The concerns are like cranes and the addition of safety concerns due to the site-built structure.

### Research Objectives

The objective of this paper is to document the design, analysis, and prototype of the Material Lift

Machine (MLM). The MLM must fit on a regular car or SUV trunk without special attachments or carriers. To be easily loaded to a trunk It must weigh under 60 lbs. The MLM must have the capacity to transport loads up to 200 lbs. to two story building roofs. To be easy to maneuver it must be a one-person operation. For safety it must be self-leveling while operating.

### Research Contributions

This research adds to limited information on the application of commercial and industrial climbing robot technology to solve residential and small business problems. It has the purpose of improving safety on DIY projects or small service contractors by providing a portable and easy to storage lifting mechanism. By making it a 1-person operation it minimizes human effort while improving efficiency. While it requires an initial investment, the MLM will help to maintain low cost of labor for contractors.

### LITERATURE REVIEW

Elevators are traced back to the 236 B.C. where the roman Architect Vitruvius reported that Archimedes built his first elevator [7]. Elevators were not invented for human transport but for raw material animals, and cargo. Elevators lacked security features and regulations and were powered by men or animals. The material Lift Machine is a trip back in time to the origins of the elevator but with a modern twist. The MLM provides a way to lift materials to high places by way of disposable two-by-four lumber. The two by four lumbers are used to provide the structure of the Material lifter machine. A threated two “ x 4” pine lumber can support up to 300 lbs. on its edge and up to 1000 lbs. vertically [8]. This material is available as standard dimension lumber in most hardware stores at exceptionally low prices. Also is a common material found on construction sites.

By displacing the center of mass of the system away from the contact points as shown on Figure 4, a tangential force is created. This concept has been utilized for pole climbing boots, tree pruning robots,

and flagpole mechanism. A more compact and specific application is presented on this paper. Gravity plays a key role in the functioning of this system.

**Figure 4**  
Forces Acting on Lifter

### METHODOLOGY

The MLM is inspired by the old ways of climbing trees shown on Figure 5 where the man is exerting a force equal to his weight normal to the palm tree. The friction between his leather covered feet and palm tree surface provides a few seconds to reposition upper rope at higher position and pull himself up. Friction is the result of the normal force created by weight and the rope against the surface and the coefficient of friction of his feet and the rope.

**Figure 5**  
Climbing on Palmyra Tree[9]

Two 2x4s leaned at 75° from the floor are fed to the MLM. The machine will clamp the wood member by leveraging the distance of the center of mass from the driving wheel contact point and

generate a moment forcing the driven wheel against the wood member on the other side. On Figure 6 the forces acting on the lifter are depicted and analyzed to determine the required conditions to achieve static equilibrium.

**Figure 6**  
Forces Acting on Lifter

The MLM is recommended to lean at 75° from the floor. To obtain a non-slip condition at the footing of the MLM The following calculations are required, the coefficient of static friction between the MLM footing and the floor is  $\mu=0.7$

Force of friction equals weight times coefficient of friction. The coefficient of friction is found experimentally and tabulated.

$$F_f = W * \mu \quad (1)$$

Where  $F_f$  is friction force,  $W$  is weight and  $\mu$  is the coefficient of friction between the two materials in this case wood and rubber. Utilizing the sum of forces in the y and x direction along with the sum of moments the forces acting on the carriage basket are determined.

$$\sum F_x = F_f - N_1 = 0 \quad (2)$$

$$\sum F_y = N_2 - W_s - W_w = 0 \quad (3)$$

$$N_2 = W_s + W_w \quad (4)$$

$$CW + \sum M_A = 0 \quad (5)$$

$$W_s * \cos(\theta) * l + W_w * \cos(\theta) * \frac{l}{2} - N_2 * \cos(\theta) + F_f * \sin * l \quad (6)$$

Divide by  $\cos(\theta)$  to get:

$$\tan(\theta) = \frac{-W_s - \frac{W_w}{2} + N_2}{F_f} \quad (7)$$

The posts exert normal forces of equal magnitude but opposite directions due to moment generated by the weight hence (8).

$$N_{F1} = N_{F2} \quad (8)$$

A tangential force ( $T_F$ ) will be generated at point of contact 1 ( $P_{C1}$ ) equal to the weight ( $W$ ) of the carriage. Weight is the product of mass ( $m$ ) times the acceleration of gravity ( $g$ ). Hence 2.

$$T_F = W = mg \quad (9)$$

The angle ( $\theta$ ) formed with segment  $P_{C1}$ - $P_{C2}$  and a line normal to the wood member is obtained.

$$\theta = \arccos\left(\frac{t}{b}\right) \quad (10)$$

The moments respective  $P_{C1}$  generates an equation to find  $F_{N2}$ .

$$mga \cos(\theta) = b \sin(\theta) N_{F2} \rightarrow N_{F2} = \frac{mga}{b \tan(\theta)} \quad (11)$$

The non-slipping condition at  $P_{C1}$  is obtained utilizing the Coulomb friction law where it states that a coefficient of friction ( $\mu$ ) times a normal force gives the friction force ( $f$ ). The friction force must be equal or greater than the tangential force to make the wheels roll without slipping on the edge of the two-by-four.

$$\mu N_{F1} \geq T_F \quad (12)$$

The magnitude of the normal force 1 ( $N_{F1}$ ) is unknown but it should be greater than the tangential force per the coefficient of friction.

$$N_{F1} \geq \frac{T_F}{\mu} \rightarrow \frac{mg}{\mu} \quad (13)$$

To obtain the magnitude of normal force 1 ( $N_{F1}$ ) (8) and (11) are combined and rewritten to obtain (14).

$$N_{F1} = \frac{a m g}{b \tan(\theta)} \quad (14)$$

Equation (15) will provide the minimum angle allowed to obtain a no slip condition.

$$a \geq \frac{b \tan(\theta)}{\mu} \quad (15)$$

After obtaining a non-slip condition attention is paid to the electronics. An Arduino UNO [10] controls the input and outputs while a pair of two 350W permanent magnet DC motors provide the lifting power. The motors require a 24V to operate therefore a 24V motor driver and external power source are required since the microcontroller only provides 5V output. The L298N [11] is chosen for this application since it can run both motors with an external power supply.

Figure 7  
Carriage Deflection[7]

From Figure 7 force BC is obtained by applying moment equilibrium about point A.

$$\sum CCW + \sum M_A = 0 \quad (16)$$

$$F_{BC} * \sin(\theta) * \overline{AB} - \overline{AB} * W = 0 \quad (17)$$

$$F_{BC} = \frac{\overline{AB} * W}{\sin(\theta) * \overline{AB}} \quad (18)$$

With the force ( $F_{BC}$ ) we calculate the deflection of segment BC with (19)

Where  $P$  y tension force on segment BC,  $L$  is length of segment BC,  $A$  is for cross section Area and  $E$  is the modulus of elasticity.

$$\delta_{BC} = \frac{PL}{AE} = \frac{F_{BC} * \overline{BC}}{A * E} \quad (19)$$

With the deflection of segment BC, the Pythagorean Theorem is used to determine the new angle  $\beta$ .

$$a^2 + b^2 = c^2 \quad (20)$$

$$(\overline{BC} + \delta_{BC})^2 = (\overline{AC})^2 + (\overline{AB})^2 - \overline{AC} * 2\overline{AB} * \cos(\beta) \quad (21)$$

$$1 = \cos^{-1} \left( \frac{(\overline{BC} + \delta_{BC})^2 - (\overline{AC})^2 - (\overline{AB})^2}{-2\overline{AC} * \overline{AB}} \right) \quad (22)$$

$$\delta_{AD} = (\beta - 90) * \overline{AD} \quad (23)$$

Figure 8  
Static analysis on MLM[8]

The sum forces in the x and y direction along with the sum of momentum in terms of A provide the minimum angle required to lean MLM against the wall as shown on Figure 8. In this case  $\mu_s$  is the static coefficient of friction between rubber and wet concrete.

$$F_{fB} = \mu_s * B_x \quad (24)$$

$$F_{fA} = \mu_s * A_y \quad (25)$$

$$+ \sum F_x = 0 \quad (26)$$

$$F_{fA} - B_x = 0 \therefore A_y = \frac{B_x}{\mu_s} \quad (27)$$

$$\uparrow + \sum F_y = 0 \quad (28)$$

$$F_{fB} + A_y - W_L = 0 \therefore W_L = \mu_s * B_x + A_y \quad (29)$$

From (27) we obtain new value for  $A_y$  and incorporate on (29) to obtain

$$W_L = \mu_s B_x + \frac{1}{\mu_s} B_x \therefore W_L = B_x \left( \mu_s + \frac{1}{\mu_s} \right) \quad (30)$$

$$\text{or } B_x = \frac{W_L}{\left( \mu_s + \frac{1}{\mu_s} \right)} \quad (31)$$

$$CCW + \sum M_A = 0 \quad (31)$$

$$-\cos(\theta) * W_L * l + \sin(\theta) * B_x * l + \cos(\theta) * F_{fB} * l = 0 \quad (32)$$

Substituting (24) in (32) and rewriting we obtain:

$$-\cos(\theta) * W_L * l + \sin(\theta) * B_x * l + \cos(\theta) * \mu_s * B_x * l = 0 \quad (33)$$

$$\sin(\theta) * B_x * l = \cos(\theta) * B_x \left( \mu_s + \frac{1}{\mu_s} \right) * .9735l - \cos(\theta) * \mu_s * B_x * l \quad (34)$$

Dividing by  $\cos(\theta) * B_x * l$  on both sides the equation becomes:

$$\sin(\theta) = \cos(\theta) \left( \mu_s + \frac{1}{\mu_s} \right) .9735 - \cos(\theta) * \mu_s \quad (35)$$

$$\tan(\theta) = \left( \mu_s + \frac{1}{\mu_s} \right) .9735 - \mu_s \quad (36)$$

The minimum angle at which the MLM can be set from the floor is given by (37).

$$\theta = \tan^{-1}(\tan(\theta)) \quad (37)$$

## RESULT AND DISCUSSION

Currently, the existing home improvement retail stores do not carry products for consumers that allow them to lift material or heavy equipment to two story house roofs. People's alternative options are to rent expensive heavy equipment or purchase a crane like equipment which is not only heavy but too big to store. If the user does not have the capital for the mentioned alternative the other ways is to carry the material up a ladder or pull it up with a rope, becoming not only a safety hazard but an inefficient time-consuming task.

A prototype has been created with alternate parts due to the costs and time constraints. Parts were manufactured at a garage with simple power tools.

Gears were extracted from manual marine winch devices while the 4:1 gear ratio was maintained. All Rectangular tubing was purchased at local retailers. Obtained 4 2 in casters from spare parts available at home and electronics from a previous sun tracker project. Driver wheels and motor were purchased online. All components together weighed approximately fifty-nine pounds. The actual MLM with all the designed components is expected to have a weight of less than 60 pounds.

By utilizing a reduction gear train as shown in Figure 9, the speed will be reduced from 2700 RPM to 42 RPM with a gear ratio of 64:1. As shown in Table 1.

**Figure 9**  
Reduction Gear Train

**Table 1**  
Train Reduction Gear Selection

Train Reduction		
Input		
Speed	2700	RPM
Torque	10.94767593	Lb.in
Power	350	W
Number of teeth		Gear Ratio
Driver Gear	15	4
Idler 1	60	
Idler 2	15	4
Idler 3	60	
Idler 4	15	4
Driven Gear	60	
Resultant Ratio		64
Output		
Speed	42.1875	RPM
Torque	700.6512593	Lb.in

According to the calculation on the different components shown on Figure 10, the deflection of the loaded carrying basket cantilever beam is expected to be 0.0965 as shown on Table 2.

**Figure 10**  
Aluminum Rectangular Cantilever Beam Deflection Analysis

A letter shown on Figure 12 answered by director Russell B. Swanson of OSHA states that because hoist is placed on ladder-like structure and is not climbed it is not subjected to ladder use requirements and the lifting activity for which is being used it is not considered a hoist of OSHA's hoisting regulation. Users must follow the fall protection requirements in accordance with 29 CFR 1926.500-503.

June 2, 1998  
Mr. Gregory C. Clements  
Business Products Company  
P.O. Box 6339  
Los Angeles, CA 90063-0309  
Re: 1926.500-503, 1926.502, 1926.1053  
Dear Mr. Clements:  
This is in response to your letter dated October 4, 1995, requesting an interpretation of the Occupational Safety and Health Administration (OSHA) standards addressing ladders used to support a hoisting wheel. Your letter references the use of a Ladder Master Hoisting Wheel, and the need to adhere to the regulations for ladder use while involved in lifting materials with the device. Ladders are required to be secured to prevent accidental displacement when employees are using them on unstable, slippery or non-level surfaces. However, when using a ladder to lift materials with a hoisting wheel, employees would not be using the ladder for climbing and therefore would not be subjected to ladder use requirements.  
When involved in this lifting activity, the ladder would not be considered a hoist for the purposes of OSHA's hoisting regulations and would therefore not be subject to the provisions of Subpart N Cranes, Derricks, Hoists, Elevators, and Conveyors. However, those employees exposed to fall hazards during lifting activities must comply with the applicable fall protection requirements in accordance with 29 CFR 1926.500-503 (i.e., safety monitor for free-dropped loads).  
We agree, if used properly and within manufacturer's guidelines, this ladder hoisting wheel could reduce or eliminate injuries from lifting heavy loads while climbing ladders.  
Thank you for your interest in job site safety and health issues and if we can be of any further assistance, please write to:  
Directorate of Construction-OSHA  
Office of Construction Standards and Compliance Assistance, RM-3182L  
200 Constitution Avenue, N.W., 8th, N3821  
Washington, D.C. 20310  
Sincerely,  
Russell B. Swanson, Director  
Directorate of Construction

**Figure 12**  
OSHA Response Letter to Hoist or Ladder Safety Standards

Results of the prototype testing and pictures will be provided after building up.

## CONCLUSION

This research presented a new application to climbing robot technologies to provide a solution for individuals looking to lift material and equipment to their two-story buildings. The governing mechanical principles have been calculated and described. The non-slip condition is dependent on the geometry of the contact points and the coefficient of friction but

not on the center mass. Later configuration will include all components as designed to lower cost and weight and upgrade performance. More capabilities can be added like battery operation, different carriage basket configurations, and ride on capabilities.
